Cloning of a wheat 15-kDa grain softness protein (GSP) GSP is a mixture of puroindoline-like polypeptides
Rahman S; Jolly C J; Skerritt J H; Wallosheck A
Commonwealth Scientific Industria, Res. Organisation, Div. Plant Industry, P.O. Box 1600, Australian Captial Territory 2601, AUL
European Journal of Biochemistry 223 (3), 1994. 917-925.
Full Journal Title: European Journal of Biochemistry
ISSN: 0014-2956
Language: ENGLISH
The wheat starch 15-kDa protein (called grain softness protein or GSP) consists of a major polypeptide and several minor polypeptides. An antiserum raised against GSP was used to screen a wheat cDNA library. A cDNA family encoding approximately 15-kDa proteins that included a heptapeptide sequence previously isolated from protease digests of GSP was identified. A partial cDNA was used in a prokaryotic expression system to produce a fusion protein which reacted strongly against the original anti-GSP serum. A new antiserum raised against the fusion protein produced a weak reaction against a 15-kDa polypeptide extracted from wheat seeds. The results suggest that the proteins encoded by the cDNA family form a minor component of the mixture of 15-kDa polypeptides defined as GSP. RNA complementary to the cDNAs could be extracted from both soft and hard wheat grains from about half-way through grain filling. The encoded proteins are novel members of the 25 superfamily of seed proteins, a diverse family of proteins which maintain a characteristic framework of cysteine residues. The deduced proteins show the highest similarity to the oat 16-kDa avenin and to wheat puroindoline (a lipid-binding 15-kDa protein from wheat). Review of previously published data shows that puroindoline is also closely

related to the major polypeptide of GSP, suggesting that the lipid-binding properties of GSP polypeptides may influence brain softness.

The emergence of a wide variety of biological expression systems for the large-scale production of therapeutic proteins has shifted the focus from vectors to host organisms. Although expression systems now span bacteria, fungi, plants, insects, and mammalian cells, the vast majority of recombinant-derived biopharmaceuticals at the present time have been produced in Escherichia coli and in mammalian cells. This promises to change as the economic benefits of the newer systems permit the development of a new generation of proteins heretofore considered unfeasible for commercial development. Despite the impressive results which have been observed for many of the newer systems, there are many commercial considerations which suggest that E. coli and CHO cell expression systems may continue to dominate the manufacture of biopharmaceuticals for a long time to come.

Language: ENGLISH
The cold-shock response of Escherichia coli K-12 cells to a sudden

of gene expression in response to abrupt shifts to lower temperatures. This pattern includes the induction of cold-shock proteins, synthesis of proteins involved in transcription and translation, and repression of heat-shock proteins. The identified cold-shock proteins are involved in various cellular functions from supercoiling of DNA to initiation of translation. The major cold-shock protein, CspA, has high sequence similarity with three other E. coli proteins - CspB, CspC, and CspD. Using translational lacZ fusions, cspB was found to be cold-shock inducible at the level of transcription like cspA, while cspC and cspD were not. The Csp proteins, which share sequence similarity with other prokaryotic proteins and with the 'coldshock domain' of eukaryotic Y-box proteins, may have a function in activating transcription or unwinding or masking RNA molecules. Because the coldshock response can also be induced by the addition of certain inhibitors of translation, it has been proposed that the state of the ribosome is the physiological sensor for the induction. In addition to E. coli, cold-shock proteins have also been found in other prokaryotic and eukaryotic organisms.

Dep. Biochem., Cent. Mol. Toxicol., Vanderbilt Univ. Sch. Med., Nashville, TN 37232-0146, USA
Archives of Biochemistry and Biophysics 306 (2), 1993, 443-450.
Full Journal Title: Archives of Biochemistry and Biophysics
ISSN: 0003-9861
Language: ENGLISH
The human cytochrome P450 (P450) 2C gene family is complex and heterologous expression methods are needed to facilitate the isolation of individual P450 proteins and the elucidation of their catalytic specificities. We prepared a series of constructs of P450 2C10 in the plasmid vector pCW, with modification of the 5' end of the coding sequence of the cDNA. Some were not expressed at all in Escherichia coli; two were expressed at levels of 5-20 nmol membrane-bound P450 (liter culture)-1-one (2C1028) with original codons 2-7 altered by substitution of the 5'-terminal sequence described by Barnes et al. (Barnes, H. J., Arlotto, M. P., and Waterman, M. R., Proc. Natl. Acad. Sci. USA 88, 5597-5601, 1991) and one (2C1029) with original codon 2 modified, codons 3-20 deleted, and alteration of the immediate downstream codons. In both cases the P450 2C10 proteins were found essentially only in the bacterial membranes. These proteins could be purified to a high degree by solubilization and a single DEAE chromatography step. Typical P450 Fe2+ ontdot CO absorption spectra were observed in the bacterial membranes and the purified preparations. The P450 2C1029 protein was found to have its N-terminal Met removed and the expected residues 2 (Ala)-24 were identified by amino acid sequence analysis. However, the other P450 (2C1028) was apparently blocked at the N-terminus. Three native P450 2C9/10 preparations isolated from human liver showed the expected sequences (beginning with Met) for at least the first 17 residues. The blocked N-terminus in the P450 2C1028 protein may be the result of the MALLLAVF sequence, which was also used in the expression of P450 3A4 and resulted in a blocked protein. Catalytic activities of P450 2C1028 and P450 2C1029 [redacted] tolbutamide hydroxylati[redacted] were similar to those measured with purified liver P450 2C9/10 in the presence of cytochrome b5,

as with the isolated liver enzyme. The recombinant P450 2C10 enzymes did not catalyze (S)-mephenytoin 4'-hydroxylation.

Escherichia coli may cause intestinal or extraintestinal infections. Generally, extraintestinal E. coli are encapsulated. The capsules are important virulence determinants, which enable the pathogenic bacteria to evade or counteract the unspecific host defense during the early (preimmune) phase of infection. They interfere with the action of complement and phagocytes. This effect is generally transient and overcome by capsule-specific antibodies in the immune phase of the host defense. In some cases, capsules are not or only poorly immunogenic, as a result of structural relationship or identify with host material. Strains with such capsules (e.g., K1 or K5) are very virulent. Bacterial capsules consist of acidic polysaccharides, which are made up from oligosaccharide repeating units. The capsules of E. coli are divided into two groups, which differ in chemistry, biochemistry, and genetic organization. All capsular polysaccharides are chromosomally determined: those of group I close to his and those of group II close to serA. The biosynthesis and surface expression have been extensively studied with representatives of group II capsular polysaccharides. It could be shown that their biosynthesis is directed from a gene block that determines the synthesis of the polysaccharide, its translocation across the cytoplasmic membrane, as well as its surface expression in a coordinate process. The chemical nature of group II capsular polysaccharides, as well as the mechanism(s) of their biosynthesis and expression, is presented.

Full Journal Title: Drugs
Language: ENGLISH

Recombinant granulocyte-macrophage colony stimulating factor (rGM-CSF) is a polypeptide hormone produced through recombinant DNA technologies in glycosylated (yeast or mammalian expression systems) or nonglycosylated (Escherichia coli expression system) form. It is a multilineage haematopoietin which stimulates proliferation and differentiation of bone marrow myeloid progenitors and increases peripheral white blood cell counts when administered systemically. Treatment is generally well tolerated, although mild to moderate flu-like symptoms are common and rGM-CSF-induced fever and fluid retention may be problematic in occasional patients. rGM-CSF accelerates recovery of peripheral neutrophil counts after bone marrow transplantation, and results of a placebo-controlled randomised trial correlate this with reduced infectious episodes and shortened length of hospitalisation in patients with lymphoid malignancies. A substantial number of patients with graft failure after bone marrow transplantation also respond to rGM-CSF. The duration of myelosuppression secondary to cancer chemotherapy can be significantly reduced by rGM-CSF which has permitted investigation of antineoplastic dose-intensity escalation. In some haematopoietic disorders (e.g. aplastic anaemia, myelodysplasia and neutropenia secondary to HIV infection and antiviral therapy), rGM-CSF produces clinically useful increases in peripheral blood granulocyte counts, although the effect is generally not sustained after drug withdrawal. The potential for rGM-CSF to stimulate proliferation of the abnormal clone in myelodysplasia and in acute myelogenous leukaemia following induction therapy is of concern. Available data suggest, however, that with appropriate monitoring and exclusion of high-risk patients this serious poential risk can be avoided, and that myelopoiesis is enhanced in such patients by rGM-CSF treatment. Recombinant colony-stimulating factors are a new therapeutic modality; hence many aspects of their use remain to be clarified. Nonetheless, as one of a small group of novel agents rGM-CSF has major potential in the management of myelosuppression secondary to cytoreductive therapy with or without bone marrow transplantation, and in amelioration of disturbed myelopoiesis. It represents an important application of biotechnology to a difficult area of therapeutics.

Full Journal Title: FASEB (Federation of American Societies for Experimental Biology) Journal
Language: ENGLISH

The hypervariable loops of an antibody molecule are supported on the relatively conserved beta-sheeted framework of the heavy and light-chain variable domains (designated VH and VL domains, respectively). Residues within and flanking these loops interact with antigen and confer the specificity and affinity of antigen binding on the immunoglobulin

molecule. Thus, the isolation and expression of VH and VL domain genes are of particular interest both for analysis of the determinants of antibody specificity and for generation of fragments with binding affinities for use in therapy and diagnosis. The PCR can now be used to isolate diverse repertoires of antibody VH and VL domain genes from antibody-producing cells from different species, including humans and mice. The genes can be expressed as either secreted or surface-bound Fv or Fab fragments, using Escherichia coli expression systems, and the desired antigen-binding specificity screened for or, preferably, selected. The use of E. coli as an expression host allows the required antigen-binding specificity to be isolated in clonal form in a matter of days. The VH and VL domain genes can also be hypermutated and higher-affinity variants isolated by screening or selection. Thus, the use of this technology should allow the isolation of novel binding specificities or specificities that are difficult to generate by hybridoma technology. It will also facilitate the isolation of human-derived Fv/Fab fragments that may be less immunogenic in therapy. This approach therefore has almost unlimited potential in the generation of therapeutics with binding of specificities to order. The fragments can be used either alone or linked to effector functions in the form of antibody-constant domains or toxins. The new technology could prove to be a method of choice for rapid and convenient production of designer antibodies.

Full Journal Title: Tetrahedron
Language: ENGLISH
In this review we present the principles behind protein overexpression in bacteria, emphasizing how this biosynthetic system can be manipulated to generate large quantities of proteins for study. In addition to the classical (molecular biological) methods for constructing protein-overproducing bacterial, we discuss our recently developed (chemical/enzymatic) method, the Expression Cassette polymerase Chain Reaction (ECPCR). The chemical/enzymatic transformation of an unexpressable to an expressable gene afforded by ECPCR can routinely be carried out in the experimental organic chemistry laboratory, hence, ECPCR offers a convenient point of entry for chemists interested in macromolecular science.
